

# CMPT-435-Assignment-2

Ahmed Handulle

October 11, 2022

In this document, I will be explaining my code from Assignment 2 in detail. It will be divided into different sections by Functions and talk about what each part will do.

## 1 External Java Packages

Below is a list of external Java packages that I have used to create my program.

```
1 import java.io.File; // This line will import the Java file utility
   package and it will give us access to other files in our
   computer. We will also use it to read data from as well as
   writing data to those files.
2 import java.util.Scanner; // This line imports the Java Scanner
   package which is a text scanner that can parse data (strings/
   numbers) using regular expressions.
3 import java.util.ArrayList; // This line also imports the ArrayList
   package which will give us many functionalities of dynamic
   arrays in Java.
4 import java.util.Random; // Importing this random class will help
   us create objects of the Random class to generate random
   numbers.
```

## 2 Class Level Variables

The following code listing describes the class level variables (global) for the Main class of this program. The two variables will be used to keep track of the number of comparisons that happen inside the merge and quick sorts respectively. The will be accessed from inside of future methods.

```
1 public class Main {
2     private static int mergeSortComparisonsCount=0;
3     private static int quickSortComparisonsCount=0;
```

### 3 Shuffling Method

The below functions takes an ArrayList as an input. The functions then shuffles all the elements in the ArrayList using a technique known as the Knuth Shuffle. The way this technique works is that it will start iterating over the list elements from the first position ( $i=0$ ) to the last ( $n-1$ ). At any given position, a random integer(index) between the ( $i$ )th position and the last position of the list will be generated. After that, the element at the position of the random index will be swapped with the element at the ( $i$ )th position. This technique eliminates all biases as all elements in the list have equal chances of being chosen as random.

```
1 public static void shuffleArrList(ArrayList<String> strList) {
2     int n = strList.size();
3     //Creating an object of the Random class in order to computer
4     //the random integer
5     Random ran = new Random();
6     //Iterating over the ArrayList
7     for(int i=0; i<n; i++){
8         //Generating a random integer; nextInt(int n) method is used to
9         //generate a random integer from the sequence of 0(inclusive) to
10        //the number passed as an argument.
11        int randomIndex = i + ran.nextInt(n-i);
12        //Then the values at the (i)th position is swapped with the
13        //one at the randomIndex.
14        String temp = strList.get(randomIndex);
15        strList.set(randomIndex, strList.get(i));
16        strList.set(i, temp);
17    }
18 }
```

### 4 Selection Sort

In the section, I will be implementing a selection sort algorithm. The function takes an ArrayList of strings as an input. This is comparison-based algorithm where the list of ( $n$ ) elements will traversed and for each iteration, the minimum element of the list will be selected and swapped with the element at the ( $i$ )th position where ( $i$ ) starts from 0- $(n-1)$ . The average and the worst case time complexities of this algorithm is of big  $O(n^2)$  where ( $n$ ) is the number of items.

```
1 public static ArrayList<String> selectionSort(ArrayList<String> str
2 ){
3     //We check if the input is empty before we start doing anything
4     //else so we can save time and computing power
5     if (str == null) {
6         return null;
7     }
8     // Then we are making a call to the shuffling method to shaffle the
9     //list before we start sorting.
10    shuffleArrList(str);
11    int comparisonCount = 0;
12    int n = str.size();
13    // This outer loop will start iterating from the first position of
14    //the list (i=0) up to (n-1) where n is the size of the list.
```

```

11     for(int i=0; i<n-1; i++){
12 // We are now considering the element at the first position as the
    minimum element.
13     int minPosition = i;
14 // The inner loop will start iterating from the element at the
    second position of the list up to the last element.
15     for(int j= i+1; j<n; j++){
16         comparisonCount++;
17 //For each (j)th iteration, we are comparing the element at the (j)
    th position with the element at our minimum position. Since we
    are using an ArrayList, we use the obj.compareTo(obj) method to
    compare the two strings. This method will return a positive
    integer if the first (obj) is greater than the second (obj)
    alphabetically, otherwise it will return a negative integer.
    Also, this method will return 0 if both the strings are the
    same. Then we will save the outcome in an int variable called
    result.
18         int result = str.get(j).compareTo(str.get(minPosition))
    ;
19         if(result<0){
20 //If the element at the (j)th position is smaller than the element
    at the minimum position, we then update the minimum position to
    the (j)th position.
21             minPosition = j;
22         }
23     }
24 // After the minimum element is found, then it will be swapped with
    the element at the (i)th position.
25     String temp = str.get(i);
26     str.set(i, str.get(minPosition));
27     str.set(minPosition, temp);
28 }
29 System.out.println("Number of Comparisons: "+ comparisonCount);
30 return str;
31 }

```

## 5 Insertion Sort

Insertion sort is another comparison-based algorithm which is slightly different than selection sort. For insertion sort, a sub-list is sustained which is always sorted. The sorted list first starts with one element which is usually the first element, and the rest of the list is considered to be unsorted. The elements in the unsorted list will be selected one by one and then inserted into their proper position in the sorted list, which usually start at the left end of the list by swapping with the next element. The following function takes an ArrayList as a list of strings.

```

1 public static ArrayList<String> insertionSort(ArrayList<String> str
    ){
2     if (str == null) {
3         return null;
4     }
5     shuffleArrList(str);
6 //Here, I'm using two variables to count the number of comparisons.

```

```

7     int swapComparison = 0;
8     int nonSwapComparison = 0;
9     int n = str.size();
10    // This outer loop will iterate over all the elements in the list
        sequentially starting from the second position, since a sub-
        list of one element is already sorted, all the way up to the
        last element.
11    for(int i=1; i<n; i++){
12    //Here we are keeping truck of both the position and the value of
        the current element we want to insert into its proper position,
        since we are swapping with other elements until we find its
        position.
13        String currentValue = str.get(i);
14        int currentPos = i;
15    // For this loop, we are checking two conditions. The first one is
        that we want to iterate over the all the elements in the list
        except the first one at index 0, since we know that element is
        already in its sorted position. The second condition is where
        we compare the element at our current position with the element
        with its preceding element.
16        while((currentPos>0) && (str.get(currentPos-1).compareTo(
            str.get(currentPos))>0)){
17    // We swap the elements if they satisfy both conditions and keep
        repeating this process until we find it is proper position or
        we reach the last position at index 0.
18        str.set(currentPos, str.get(currentPos-1));
19        str.set(currentPos-1, currentValue);
20    // Here we increment the number of comparisons when the condition
        in the while loop is true
21        swapComparison++;
22    // We decrement the current position index since we are looking for
        the correct position in the sorted sub-list , which is at the
        left side of the list.
23        currentPos--;
24    }
25    // Here we also increment the number of comparisons in case the
        while is condition is false because we are doing comparisons in
        the while loop condition.
26        nonSwapComparison++;
27    }
28    System.out.println("Number of Comparisons: "+ (swapComparison+
        nonSwapComparison));
29    return str;
30 }

```

## 6 Merge Sort

Merge sort is a sorting algorithm that is based on divide and conquer technique with worst time complexity being big  $O(n \log n)$ . In merge sort, the list is divided into halves each time until each sub-list becomes one single element. Then the sub-lists of single elements are combined in a sorted manner until we get one sorted list. Merger sort also uses recursion for both dividing and conquering the list. The following function (mergeSort) takes an ArrayList of strings as an argument.

```

1 //The following function is an extra step and somehow unnecessary
  but I used it to make the program readable and easy to follow.
  So the function just takes an ArrayList of Strings as an input.
2 public static ArrayList<String> mergeSort(ArrayList<String> str) {
3     if (str == null) {
4         return null;
5     }
6     shuffleArrList(str);
7 // After shuffling the input, We are calling the actual merger sort
  and passing three arguments. The first one is the inputer (
  ArrayList of strings), the index of the first element is the
  second argument and finally the index of the last element of
  our list.
8     mergeSort(str, 0, str.size()-1);
9     System.out.println("Number of Comparisons: "+ (
  mergeSortComparisonsCount));
10    return str;
11 }
12 // This function is being called from the preceding function with
  arguments passed to it.
13 public static void mergeSort(ArrayList<String> str, int
  leftEndIndex, int rightEndIndex) {
14 // Checking to see if we have more than one element in our input
  list by comaring the indices of the first element element to
  the last index of the last element of the list.
15     if(leftEndIndex<rightEndIndex){
16 // To divide the list in two halves, we have to find the mid point
17         int mid = (leftEndIndex+rightEndIndex)/2;
18 // We are then calling the mergeSort recursively by passing three
  arguments, the input list, the leftmost index and the mid point
  index of the list. We continue calling the mergeSort until the
  left halve of the list is broken down into a sub list of
  single element.
19         mergeSort(str, leftEndIndex, mid);
20 // The samething is done for the right half of the list.
21         mergeSort(str, mid+1, rightEndIndex)
22 // Most of the work happens here by calling the merge sort function
  .
23         merge(str, leftEndIndex, mid, rightEndIndex);
24     }
25 }
26 // The Merge sort function combines the sub-lists into a single sub
  -list in a sorted manner. It takes an ArrayList of Strings as
  an input as well as leftmost, rightmost and mid indices.
27 private static void merge(ArrayList<String> str, int leftEndIndex,
  int mid, int rightEndIndex) {
28 // Here we create an empty ArrayList data structure for merging the
  sub-lists since we can't use our original list to merge the
  sub-lists because there are more than two sub-lists. We then
  copy the elements of the original list into the new temporary
  list because we can't access the indices of an empty list.
29     ArrayList<String> tempArray = new ArrayList<String>(str);
30     int i = leftEndIndex;
31     int j = mid+1;
32     int tempArrayIndex = leftEndIndex;
33 // Here, we are using a while loop to iterate over every two sub-
  lists by comparing the their values to each other and placing

```

```

        each value in the sub-list onto the temporary ArrayList we have
        created for storing sub-lists.
34     while((i<= mid) && (j<=rightEndIndex)){
35 // We check if the left left sub-list at index (i) is smaller than
        the one in the right.
36         if(str.get(i).compareTo(str.get(j))<0){
37 // Since the condition is true, we copy the value at index (i) in
        the sub-list into the temporary ArrayList of strings.
38             tempArray.set(tempArrayIndex, str.get(i));
39 // We then increment the index of the left sub-list
40             i++;
41
42         } else {
43 // Since the condition is false, it means the element at index (j)
        in the right sub-list is smaller and that element will be
        stored in the temporary ArrayList at index (j)
44             tempArray.set(tempArrayIndex, str.get(j));
45 // We then increment the index of the right sub-list
46             j++;
47         }
48 // We are also incrementing the index in the temporary ArrayList
        since we place an element at the current index
49         tempArrayIndex++;
50         mergeSortComparisonsCount++;
51     }
52 // In the following loop, we check if there any visited elements
        left in the left sub-list in case the right sub-list traversal
        finished before the left-sub-list.
53     while (i<= mid){
54 // Since the condition is true, we finish iterating over the rest
        of the elements in the left sub-list and just put them in the
        temporary list since there are no element to compare with from
        the right sub-list.
55         tempArray.set(tempArrayIndex, str.get(i));
56         i++;
57         tempArrayIndex++;
58     }
59     while (j<=rightEndIndex) {
60 // We do the same thing for the right sub-list in-case the left sub
        -list are visited before the right sub-list iteration is
        finished and just put them in the temporary list.
61         tempArray.set(tempArrayIndex, str.get(j));
62         j++;
63         tempArrayIndex++;
64     }
65 // Now, we are iterating over the temporary ArrayList, which stored
        the sorted list and copy element back into their original
        ArrayList.
66     for(int x=leftEndIndex; x <rightEndIndex+1; x++){
67         str.set(x, tempArray.get(x));
68     }
69 }

```

## 7 quickSort Sort

Quick Sort is another sorting algorithm that is based on partitioning of list of data into smaller lists. At first step, a larger list will be partitioned into two sub-lists with one sub-list holding values smaller than a specific value, a pivot, and the other sub-list holding values greater than the pivot value. Then, the algorithm uses recursion to sort the two sub-lists recursively. Also, this algorithm takes big  $O(n \log n)$  on an average case but it can go down to big  $O(n^2)$ .

```
1 // The following method takes an ArrayList of strings as an
  // argument and I'm using it to make an easy call to the actual
  // quick sort function.
2 public static ArrayList<String> quickSort(ArrayList<String> str) {
3     if (str == null) {
4         return null;
5     }
6     shuffleArrList(str);
7 // After shuffling the list, we make a call to our actual sort
  // function and pass three arguments as the ArrayList of strings,
  // position of the first element of the list, and the position of
  // the last element of the ArrayList respectively.
8     quickSort(str, 0, str.size()-1);
9     System.out.println("Number of Comparisons: "+ (
        quickSortComparisonsCount));
10    return str;
11 }
12 public static void quickSort(ArrayList<String> str, int
    leftEndIndex, int rightEndIndex) {
13 //Here, I'm making sure that the left most position of the list is
  // always less than right most position, if not then we know that
  // we have partitioned all the elements of the list.
14     if (leftEndIndex<rightEndIndex){
15 // Once the above condition is true, we are going to divide the
  // partition the larger ArrayList around a specific value. To do
  // that we are making a call to the partition function which will
  // return the position of the specific value that we partitioned
  // around the elements.
16         int partitionIndex = partition(str, leftEndIndex,
            rightEndIndex);
17 // Then, we keep partitioning the sub-lists until we get to sub-
  // list of one element.
18         quickSort(str, leftEndIndex, partitionIndex-1);
19         quickSort(str, partitionIndex+1, rightEndIndex);
20     }
21 }
22 public static int partition(ArrayList<String> str, int leftEndIndex
    , int rightEndIndex) {
23 // Since we are shuffling the list before we start sorting, then I
  // have decided to pick the first element of the ArrayList as the
  // pivot and store it in a string variable called pivot.
24     String pivot = str.get(leftEndIndex);
25     int i = leftEndIndex+1;
26     int j = rightEndIndex;
27 // I'm using a while loop here that will always execute until we
  // find the position of the partitioned element. Then we will
```

```

        break out the loop once we find that.
28     while(true){
29 // I'm also using another while loop to increment the the (i)th
        index which is on the left sub-list and will compare its values
        with the pivot. This loop will terminate if the value at the (
        i)th index is greater than pivot.
30         while((i<=j) && ((str.get(i).compareTo(pivot))<=0)){
31             i++;
32             quickSortComparisonsCount++;
33         }
34 // I'm also using another while loop to increment the (j)th index
        which is on the right sub-list and will compare its values with
        the pivot. This loop will terminate if the value at the (j)th
        index is less than pivot. Because, we want to keep all the
        value greater than the pivot on the right as well as keeping
        the ones less than the pivot on the left side.
35         while((i<=j) && ((str.get(j).compareTo(pivot))>0)){
36             j--;
37             quickSortComparisonsCount++;
38         }
39 // When both while loops terminate, we need to swap the element at
        the (i)th index with the one at (j)th index since they didn't
        satisfy the conditions in the above two while loops.
40 // Before we swap the elements, we have to check if there are still
        some elements that we didn't visit using this condition in the
        following if statement (i<=j)
41         if(i<=j){
42             String temp = str.get(i);
43             str.set(i, str.get(j));
44             str.set(j, temp);
45         } else {
46 // When all elements are traversed, then we breaking out the outer
        loop, which also means that we have found the position of the
        portioning element
47             break;
48         }
49     }
50 // Then we swap the element at the position of the portioned
        element with the first element in the ArrayList which we chose
        as our pivot.
51     String tempVar2 = str.get(leftEndIndex);
52     str.set(leftEndIndex, str.get(j));
53     str.set(j, tempVar2);
54 // we just then return the position of the partitioned element
55     return j;
56 }

```
